

Complaint to TGA: Muscle Peptides Australia

On 23 July 2018, in an email to John Skerritt and Jenny Francis (TGA), I noted the outcome of the court case against [Peptide Clinics Pty Ltd](#) and suggested more court actions were needed. One of the companies I suggested was [Muscle Peptides Australia](#).

On 26 July 2019 I filled out the [online registration, assessment and “medical consultation”](#) page of Muscle Peptide Australia. I stated that I was a 75-year-old male, interested in most of the products they were offering, that I was not an athlete in a sport that subscribes to the WADA World Anti-Doping Code, and I had no significant medical history.

On 29 July 2019 my account was approved (appendix I). The appended products were available for purchase and delivery. These include Schedule 4, prescription only products such as Clomid, Nolvadex and HCG and other illegal and unapproved SARMS and peptides.

I urge the TGA to take urgent legal action against this company.

Description

Us

GHRP2 Growth Hormone Releasing Peptide – 2 (GHRP2)

GHRP-2 is a Growth Hormone releasing peptide and is similar to the GHRP-6/CJC1295, it allows for the same lean muscle to be produced but doesn't make you hungry which is sometimes a small symptom of the GHRP-6

Benefits

It enhances endurance

Makes the heart strong

Decreases fat via lipolysis

Inhibits the uptake of glucose by the liver and thus works in opposition to insulin

Helps to maintain the function of the pancreas

Stimulates the process of glucogenesis by the liver

It increases the retention of calcium and thus makes the bone strong by enhancing bone mineralization.

GHRP-2 strengthens the immune system

Boosts production of IGF-1 which offers an anabolic (muscle building) effect in turn

Speeds up the wound healing or healing following a surgery

Improves sex desire and drive and it does so by hypothalamus stimulation

GHRP-2, like its brother GHRP-6, is a hexapeptide that is a pure growth hormone secretagogue. In addition, GHRP-2 is a synthetic agonist of ghrelin. Unlike GHRP-6, this peptide does not bring on the heavy hunger side effects associated with GHRP-6; however, some users will notice slight increases in hunger. Somewhere in between GHRP-6 and iPamorelin, this hexapeptide has the ability to be a serious contender when considering which GHRP to use with your GHRH

Growth Hormone Releasing Peptide-2 (GHRP2) is a peptide made up of just 6 amino acids, which stimulates secretion of endogenous GH. Research shows GHRP2 can stimulate the pituitary to increase secretion of GH by 7-15 times, stimulating ghrelin receptors. GHRP2 acts as a synthetic ghrelin analogue (without the hunger effects). Specifically, GHRP2 will increase the number of somatotropin in a GH pulse by limiting the amount of the somatostatin present while standard GHRH increases the amplitude at which the pituitary cells pulse.

The main effects of GHRP2 are GH secretion, fat mass decrease and muscle mass increase, lowering of cholesterol level, skin and bone strengthening, protection of the liver and anti-inflammatory action.

GHRP2 possesses many repair properties that can be attributed to its immune boosting function.

Us

GHRP-6 – Growth Hormone Releasing Peptide 6 (GHRP-6)

GHRP-6

Firstly, to clarify this peptide, GHRP-6 is a peptide a Growth Hormone Releasing hexapeptide, it's a 28 amino acid peptide, and it works by signaling to the pituitary gland to begin secreting Growth Hormone.

GHRP-6 lacks opioid activity, but you get a huge pulse, (dose dependent) in your own GH levels, and you get the effects of the increased IGF-1 secreted by the liver. Now both the increased GH and IGF-1 are highly desirable for athletes, bodybuilders and those looking to improve their own physique.

GHRP-6 is a true Gh secretagogue. It is a mimetic and analog Ghrelin. Ghrelin is produced predominantly by cells in the fundas of the stomach. It increases just before a meal and decreases after a meal. It is a potent stimulator of GH production and release from the anterior pituitary gland, by acting on the GH secretagogue receptor (called the Ghrelin receptor). This is in contrast to the GHRH peptides (like CJC1295) which act on the GHRH receptor.

The increase in GH secretion due to GHRP6 (and other GHRP) leads to an increase in IGF-1 (though to be the anabolic mechanism of GH) As we get older GH and subsequently IGF-1 decrease substantially. This decline is thought to be one of the major causes of the ageing process. By increasing these levels again there is increased collagen synthesis, promotion of lean muscle mass, bone strength, improved healing capability, improved sleep cycle, increased energy, repair and regeneration of internal organs, strengthening of joint/cartilage/connective tissue, and anti aging effects on the skin. GHRP-6 has been shown in studies via a different pathway to IGF-1 to neuroprotective.

Ghrelin has potent lipogenic properties. The Growth hormone releasing peptides available have variable levels of the lipogenic behaviour. GHRP6 stimulated appetite, which has obvious health benefits in those wishing to gain weight. It does slow some lipogenic property when administered at time of high insulin levels. To avoid this and lead to more lean muscle production it is often given before meals.

GHRP-6 (and other GH releasing peptides) are synergistic with GH releasing hormones (for example CJC1295). This synergy is because they work on different receptors to lead to the production and release of GH. GHRP6 also suppresses somatostatin, which has the inhibitory effect on GHRH. GHRP6 also leads to an increase of GH production and release per each somatotrope (cells in the anterior pituitary that produce and release GH).

From this there is a lot of potential for GHRP6 to improve our health and other anti aging processes. By increasing GH and IGF-1 we can feel better, and lead potentially healthier lives.

Description

Us

HCG

HCG assists with activating your own natural production of testosterone in the body. This is used for people with low testosterone levels based on blood tests as well as PCT (post cycle Therapy)

BENEFIT FOR WOMEN

With HCG, your body has a constant and steady supply of energy. This keeps you from feeling hungry, tired, weak, or irritable. HCG also improves your metabolism. When dieting without HCG, and especially when eating only a couple meals a day, your body thinks you are starving, your metabolism slows down, you become hungry all the time, and your body begins to store any extra calories it may get because it does not know when the next meal will come or if it will be big enough to satisfy its nutritional requirements. And when you are done dieting without HCG, your body stays in that defensive mode of increased hunger, decreased metabolism, and storing all the calories it can until you have gained back all the weight you have lost and sometimes more. It does this as a precaution in the event that you should ever "starve" again, or in other words go on another diet. This does not happen with HCG. On the HCG weight loss program from Bio-Marix Weight Loss, a natural hormone is telling your body to mobilize and utilize its own reserves, filling the blood stream with a constant supply of energy and nutrients. This enables you to diet safely and comfortably lose up to a pound or more every day until you reach a healthy weight which we teach you how to maintain with our free Maintenance Program.

BENEFIT FOR MEN

Many men turn to HCG to top up their testosterone tank. Many often find their tank is nearing empty and they need a boost to help the little guys jump-start more production HCG is extremely effective for helping to boost testosterone levels because LH is usually only active during sleep. HCG also makes androgen receptors more responsive to allow for sexual dysfunctions to be corrected due to the increase in growth hormones released by the pituitary gland. This means that while your testosterone levels are increasing, androgen activity is increased to improve penile growth, positive sperm count, and testicular growth. HCG can be injected and administered to stimulate the right dose of healthy testosterone production without a change in sleep behavior or interfering with the activities of your day.

- Increase red blood cells
- Support the cardiovascular system
- Increases flow of blood and oxygen
- Healthy body hair growth
- Weight loss, reduction of fat mass
- Increased energy levels, endurance, and performance
- Increase in lean muscle mass and muscle strength
- Reduced risks of obesity
- Improved oxidation in the groin area
- Increase in libido
- Improved penile growth due to oxidation
- Proper stimulation to continue boosted sexual desire
- Proper stimulation to improve endurance and sexual performance
- Reduced risks of erectile or other sexual dysfunctions
- Increase in bone density
- Reduced risks of arthritis-related conditions

Pulsatile secretion of the gonadotropin releasing hormone (GnRH) from the hypothalamus is required for both the initiation and maintenance of the reproductive axis in the human. Pulsatile GnRH stimulates the biosynthesis of Luteinizing hormone (LH) and follicle stimulating hormone (FHS) that in turn initiates endogenous testosterone production and spermatogenesis as well as systemic testosterone secretion and virilisation. Failure of this episodic GnRH secretion or disruption of gonadotropin secretion results in the clinic syndrome of hypogonadotropic hypogonadism (HH).

The usage of anabolic androgenic steroid (AAS) may result in a functional form of HH known as Secondary Acquired Hypogonadotropic Hypogonadism and is diagnosed in the setting of low a testosterone level and sperm count in association with low or inappropriately normal serum LH and FHS concentrations.

Complaint to TGA: Muscle Peptides Australia

Description

Us

SARMS – Selective Androgen Receptor Modulators (SARMS – s22)

They are intended to have the same kind of effects as androgenic drugs like anabolic steroids but be much more selective in their action, allowing them to be used for many more clinical indications than the relatively limited legitimate uses that anabolic steroids are currently approved for.

the benefits

- Similar effects to testosterone in men (libido, strength gains, fat loss etc...)
- No conversion to Estrogen
- weight loose for women
- Legal

Selective androgen receptor modulators (SARMS) provide the benefits of traditional anabolic steroids/testosterone while minimising the side effects that these medications are we'll renowned to cause. SARMS can target specific tissue only (like muscle, bone, fat cells) by acting on the Androgen Receptor (AR) and minimise effect on target areas (like prostate, hair line, sebaceous glands.) The Androgen Receptor is a steroid receptor that is present In many places in our body (including bones, muscles, liver, organs, skin,tendons,prostrate, reproductive and central nervous systems). The effect on these regions are categorised either as androgenise (the effects on the secondary sex organs) or anabolic (the effects on muscle and bone) SARMS are tissue selective which can increase the wanted effects without the unwanted androgenic adverse effects. This means the positive effects like building muscle, strengthening bone, fat metabolism, enhanced libido and joint/tendon regeneration and repair occur, but the adverse effects are reduced significantly (including enlarged prostate, heart damage, acne, hair Loss, fluid retention, high blood pressure, enlarged male breast tissue.

The other reason that the side effects are minimised is because unlike steroids/testosterone, SARMS do not convert to oestrogen and di-hydrotestosterone (DHT)

It has been seen that with SARMS, endogenous testosterone level is not affected. There is no negative feedback mechanism that is often observed with testosterone supplementation. If this occurs the body will turn off its own production which or many men can lead to impotence (which can be long lasting even when they have stopped taking testosterone).

Supplementing with Creatine increases the effectiveness of SARMS. Creatine increases certain growth factor levels (IGF-1)' bone density and lean body mass. It also helps prevent the release of homocysteine which helps reduce any cardiovascular side-effects. Zinc and Magnesium supplements are also helpful to improve androgen sensitivity (the receptor that SARMS attaches to) and to maintain IGF-1 at its maximum level.
